1 First Java Programs: User Input/Output, Variables and Data Types

READ ME!

1. In all exercises in this exercise set, you should ***print the last line*** in the program's output using `System.out.`**`println`**. That is, there is a line break at the end of the output.
2. A fast way to write `System.out.println();` is as below:
   1. Type **syso**
   2. Press **Ctrl + Spacebar**
3. **READ THIS:** 👉 Keep pressing **Ctrl + Shift + F** to format your source text properly! 👈

My First Program

Create a program called **MyFirstProgram** that prints text to the console as shown in the example output below.

Example output:

```
This is my first Java Program:-)
```

Numbers Program

Create a program called **NumbersProgram** that prints integers between -1 and -20 as shown in the example output. Please use a **for loop** in your program.

Example output:

```
-20 -19 -18 -17 -16 -15 -14 -13 -12 -11 -10 -9 -8 -7 -6 -5 -4 -3 -2 -1
```

Welcome Program

Create a program called **Welcome Program** that first inputs a person's name, title, and a greeting phrase. Then the program should print a greeting as shown in the example output.

Example output:

```
Enter name: Jones
Enter title: Mr
Enter phrase: Welcome

Welcome Mr Jones
```

👉 Keep pressing **Ctrl + Shift + F** to format your source text properly!

Person Program

Create a program called **PersonProgram** that first inputs age, given name, and profession from the user. Then the program should print the inputted data as shown in the example output.

Example output:

```
Enter age: 27
Enter given name: Wendy
Enter profession: dentist

Wendy is a dentist who is 27 years of age.
```

Sales Program

Create a program called **SalesProgram** that first inputs the price of the product (integer), product name and discount (integer) from the user. Then the program should print the product's selling price as shown in the example output.

Example output:

```
Enter price: 150
Enter product name: ukulele
Enter discount: 30

The selling price of a ukulele is 120 euros.
```

Arithmetic Program

Create a program called **ArithmeticProgram** that first inputs two integers and one decimal number from the user. Then the program should do three separate multiplications and show their results as shown in the example output.

- The program should accept both comma and dot as decimal part separator.
- The program should not format numbers for printing.

Example output:

```
Enter an integer: 2
Enter another integer: 3
Enter a decimal number: 2,5

2 * 3 = 6
2 * 2.5 = 5.0
2.5 * 2.5 = 6.25
```

👉 Keep pressing **Ctrl + Shift + F** to format your source text properly!

Decimal Program

Create a program called **Decimal Program** that first inputs two decimal values from the user. Then the program should multiply the values together and print the calculations as shown in the example output.

- The program should accept both comma and dot as decimal part separator.
- **NB! Viope *automatically prints comma as the decimal separator* when you format decimal values as explained in the course materials**.

Example output:

```
Enter a decimal number: 2,5
Enter a decimal number: 3,1415926

2,50 * 3,14 = 7,85
2,50 * 3,14 = 7,853981
```

Language Program

Create a program called **LanguageProgram** that prints text to the console as shown in the example output below.

Example output:

```
Python is named after the "Monty Python's Flying Circus",
a BBC comedy series from 1970s.
```

Hint: See the examples of string literals in the course material.
